EFFECTIVENESS RATE OF
PRODUCTS IN CONNECTION
WITH ALTERNARIA

Recommendations

There are a limited number of eradication strategies.

During the growing season, it is necessary to limit all factors that cause plant ageing (viral diseases, water or digestive stress).

It is essential to not use only fungicides that prevent potato blast. After the flowering of potato crops, first of all, the compounds against alternaria should be used, because the plants become more sensitive.

Mancozeb is one of the compounds that are effective for *Alternaria solani*. Other dithiocarbamates (maneb, metiram), chlorothalonil etc. are also effective. At the end of the season, the use of products containing such compounds is recommended.
